The optical properties of potash doped lead chloride (PbCl₂) have been studied by sol gel technique. The optical properties of the materials were determined using a JENWAY 6405 UV-VIS spectrophotometer operating at a wavelength range of 200nm to 1200nm at an interval of 5nm. It was observed that the crystals are optically transparent. The average refractive index (n) is between 0.6 and 2.9. The refractive index greater than 2.0 makes the crystals good materials for protective coatings. The band gaps are from 3.9 to 5.0 showing that they are wide band gap materials and are good refractory materials.

(Received February 6, 2012; Accepted June 15, 2012)

Keywords: Sol gel, Optical Properties, Silica Model and Local Impurities.

1. Introduction

Sol-gel is a liquid based deposition technique, [Hench et-al., (1990) and Klein, (1994)]. It is a wet chemical technique widely used in the fields of materials science and ceramic engineering primarily for the fabrication of materials starting from a chemical solution which acts as the precursor for an integrate network (or gel) of either discrete particle or network of polymers, Allman, (1983). A gel is a colloidal system in which the dispersed substance forms a continuous, ramifying, space-enclosing cohesive framework, Thewils, (2000). The gel medium prevents turbulence, and remaining chemically inert, provides a three-dimensional structure which permits the reagents to diffuse at a desirable controlled rate.

Sol gel is used in the manufacture of multi component glasses, coatings, fibres monoliths, thermal insulation materials, controlled particle size powders, as well as special types of ceramics such as electronic ceramics, superionic conductors and high temperature superconductors, [Roy, (1999); Ulrich, (2004); Dardel, (2003) and Biecker et-al., (2001)]. It is also used in the study of physical, chemical, electrical and magnetic properties of some materials as described in literature [Bandgopadhyay et-al., (2002); Gracium et-al., (2003); Yoshihara (1997) and Mandla et-al., (2007)].

1.1. Lead Chloride Crystal (PbCl₂).

Lead chloride is a halide crystal which occurs naturally in the form of mineral cotunnite. It is used in the production of infra red transmitting glass and basic chloride of lead known as patteson’s white lead, Perry, (2007), ornamental glass called aurene glass, stained glass. It is also used as an intermediate in refining bismuth (Bi) ore, it is used in the synthesis of organometallic (metallecenes or plumbocenes), lead titanate and barium titanate [Aboujali, (1998) and Lowack, (1994)]. The structure of PbCl₂ is orthorhombic dipyramidal. In this work, local potash which is a polymer in nature was used as dopant.

(a) Potash

Potash is a term coined by early American settlers who produced potassium carbonate by evaporating water filtered through wood ashes. The ash like crystalline residue remaining in the large iron pots was called ‘potash’ and was used in making soap. Potash (or carbonate of potash) is an impure form of potassium carbonate (K₂CO₃) mixed with other potassium salt. Potash has been used since antiquity in the manufacture of soap, glass and fertilizer, Nichol, (2008). Top-down approach was used to put potash into nano scale. Local potash is got by burning woods like tree fiber (ngu).

2. Experimental details

In growing (PbCl₂), 100ml beaker was added with 25ml of sodium silicate solution of pH eleven. It was titrated with some quantity of 1M of tartaric acid. The mixture forms gel at pH 8. The set gel was added with 20ml of 1M of lead nitrate solution to give lead tartarate as in equation (1.1),

\[ \text{Pb(NO}_3\text{)}_2 + \text{H}_6\text{C}_4\text{O}_6 \rightarrow \text{PbH}_4\text{O}_6 + 2\text{HNO}_3 \]  

(1.1)

The lead tartarate is generated in the gel as a white column, ring system of gradually increasing thickness. The precipitation of lead tartarate completed within a fortnight. 20ml of 1N of hydrochloric acid (HCl) placed over the set gel to give,

\[ \text{PbH}_4\text{C}_4\text{O}_6 + 2\text{HCl} \rightarrow \text{PbCl}_2 + \text{H}_6\text{C}_4\text{O}_6 \]  

(1.2)

And different concentrations of potash 0.5 and 0.8 normalities of locally produced impurity were also placed over the set gel. The HCl reacted with the colloidal precipitate of lead tartarate producing lead chloride (PbCl₂) which grew down into the gel as luminescent needles. The grown crystals were dried and adequately described through optical characterization (UV-VIS analysis) and structural analysis (XRD and FTIR). The quantity of the precursor materials used is as shown on table 1.

2.1. Drying

The samples were first treated with all glass distilled water to avoid impurities and made slurry before it was introduced into a Buckner funnel covered with filter paper then attached to a suction flask connected to the vacuum pump through its nozzle. When the pump was put on it created a vacuum that allowed for the absorption of H₂O from the sample. The filter in the Buckner funnel prevented the solid from being sucked. The sample was then taken to the oven at an appropriate temperature of 104°C for 30 minutes. After which it was placed inside the desiccators to maintain dryness. CaCl₂ was used as a desiccant.

3. Results and discussions

3.1. Optical analysis

The optical studies for the sol gel grown crystals were done using a JENWAY 6405 UV-VIS spectrophotometer operating at a wavelength range of 200nm to 1200nm at intervals of 5nm. In the optical absorption study, deionised water was used as reference. The crystal samples were
dissolved in deionised water forming a colloidal solution which was then subjected to UV-VIS analysis.

3.2. X Ray Diffraction (XRD).

X ray diffraction analysis (XRD) was used to uniquely identify the crystalline phases present in the crystals and to study the structural properties. The XRD characterization of the samples was carried out using MD-10 Diffractometer, which recorded diffractograms using CuKα radiation. Diffraction patterns of the samples were recorded in the 2θ range from 10° to 72°. XRD spectra in the figures revealed that the compounds grown are crystalline in nature. For each spectrum, the crystallite size D, was determined using the Debye Scherer formula [Haung et-al., (2006); Pradha et-al., (2005); Amma et-al., (2005); Chahal, (2010); Ezema, 2006 and Kondawar, (2010)] as given below:

\[ D = \frac{k \lambda}{\beta \cos \theta} \]  

(1.3)

Where K = 0.9 is the shape factor, λ = 1.5409Å, θ is the diffraction peak angle (Bragg’s Angle) in degrees and β is the corresponding diffraction peak. The XRD result is shown on table 5.

4. Conclusion

Sol-gel deposition technique has been successfully used to grow crystals of un-doped and potash doped lead chloride. Crystals grown in this study have made it possible for the following conclusions:

- Local materials from African environment can affect the optical and structural properties of semiconductor materials/crystals as seen in the crystallite size.
- The transparency of PbCl\textsubscript{2} decreased from 100-40\% with increasing concentration of the dopant.
- The band gap lies from 3.9eV to 5.0eV, this shows that they are wide band gap semiconductors and can be employed in high power, high temperature, high frequency materials, optoelectronic devices and as heat sink, Yacobi, (2004).
- The reduced particle size from 0.2nM to 2.5nM is a function of the broadness of the peaks and as such makes them good nano materials [Amma et-al., (2005); Chahal et-al., (2010) and Ezema (2006)]
- The sharpness of the peaks indicates that they are highly crystalline and as such are semiconductor materials that can be employed in solar energy applications.
