In the present study, forty one steroid candidates containing a pyrazole ring were screened for their anti-androgenic and anti-prostate cancer activities. Also, in the same time these compounds were screened for their EGFR and VEGFR-2 kinase inhibitor potencies comparable to that of the Delphinidin. Initially, all the candidates were less toxic than the reference drug concerning $L D_{50}$ values. Some of the compounds exhibited better antiandrogenic, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities than the reference drugs Bicalutamide and Delphinidin, respectively. The detailed antiandrogenic, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities and toxicity $\left(L D_{50}\right)$ of the synthesized compounds were reported.
(Received January 8, 2014; Accepted April 28, 2014)
Keyword: Synthetic steroids; anti-androgenic, Anti-prostate cancer, EGFR and VEGFR-2 kinase inhibitor activities.

## 1. Introduction

The steroid candidate, such as cortisone (steroid hormone, 17-hydroxy-11-dehydrocorticosterone) (Fig. 1), it is one of the main hormones released by the adrenal gland in response to stress and which suppress the antibody-forming lymphocyte cells. Also, it have been used to prolong human organ transplants and also prevent antigens from entering cells and thereby prevent local allergic inflammation reactions [1,2].

Fig. 1. Chemical structure of Cortisone

[^0]In our previous work, we found that certain of substituted steroidal and terpenoidal derivatives showed anti-androgenic, anabolic, and antioxidant activities [3-5]. Some of new steroidal derivatives fused with heterocyclic moiety have been synthesized and used as $5 \alpha$ reductase, aromatase inhibitors, anti-inflammatory, anti-alzheimer, anti-arthritic and immunosuppressive [6-12] agents.

Most signal transduction pathways were mediated by protein kinases, which was leads to proliferation of cancer cells as well as angiogenesis and growth of solid tumors such as prostate, colon, breast, and gastric cancers [13]. The VEGF family of receptors consists of three protein tyrosine kinase receptors (VEGFR-1, VEGFR-2, and VEGFR-3) and two non-protein kinase coreceptors (neuropilin-1 and neuropilin-2). These components are key intermediates in tumor angiogenesis and in the formation of new blood vessel networks required to supply nutrition and oxygen for tumor growth [14]. Vascular endothelial growth factor receptor-2 (VEGFR-2, KDR) is the main mediator that plays important roles in regulating vascular permeability, migration, endothelial cell proliferation and angiogenesis under physiological conditions mediated by the vascular endothelial growth factor (VEGF) [15]. Although VEGFR-2 has lower affinity for VEGF than VEGFR-1, VEGFR-2 exhibits robust protein tyrosine kinase activity in response to its ligands. VEGFR-2 is expressed at abnormally high levels in a large variety of human solid tumors [14,16]. There is much evidence that direct inhibition of the kinase activity of VEGFR-2 will result in a reduction in angiogenesis and the suppression of this signaling pathway has become an inhibiting method of tumor growth. Therefore, inhibition of VEGFR-2 is an attractive strategy in the treatment of cancers [17]. This research has led to the development of an USAFDA approved anti-VEGF antibody, bevacizumab (Avastin) [18], as well as three small molecule inhibitors of VEGFR-2 kinase, i.e. sorafenib (BAY-43-9006) [19], sunitinib (Su-11248) [20] and pazopanib [21] (Fig. 2). Some other small molecule, such as indolin-2-one, quinolinones, imidazopyridines, benzimidazoles, quinazolines, quinolyl-thienyl chalcones, phthalazines and quinoline amides have been reported as potent inhibitors of VEGFR-2 and angiogenesis [22-24].

## 2. Experimental

Evaluation of transcriptional activity for human androgen receptor [25]
(a) Establishment of CHO Cells Stably Transfected with Human Androgen Receptor Gene and MMTV-Luciferase Reporter Gene or SV40-Luciferase Gene: Chinese hamster ovary (CHO) cells were maintained in Alpha-modified Eagle's medium supplemented with $10 \%$ Fetal Bovine Serum (FBS). The culture medium of neomycin-resistant clone cells was supplemented with $10 \%$ dextran-coated charcoal-stripped FBS (DCC-FBS) and $500 \mu \mathrm{~g} / \mathrm{ml}$ of neomycin. The CHO cells were transfected at $40-70 \%$ confluence in $10-\mathrm{cm}$ petri dishes with a total of $20 \mu \mathrm{~g}$ DNA (pMAMneoLUC; MMTV-luciferase reporter plasmid and pSG5-hAR; human androgen receptor
expression plasmid, or SV40-LUC; SV40-luciferase reporter plasmid containing neomycin resistant gene) by calcium phosphate mediated transfection. The stable transfected cells were selected in the culture medium supplemented with neomycin. The selected clone was designated as AR/CHO\#3 (human AR gene and MMTV-luciferase reporter gene integrated CHO cell) or SV/CHO\#10 (SV-40-luciferase reporter gene integrated CHO cell), respectively.
(b) Activities of the Tested Compounds to Inhibit Androgen Receptor Mediated Transcription Induced by DHT (AR Antagonistic Activity): The stable transfected AR/CHO\#3 or SV/CHO\#10 cells were plated onto 96 well luminoplates (Packard) at a density of $2 \times 10^{4}$ cells/well, respectively. Four to eight hours later, the medium was changed to the medium containing DMSO, 0.3 nM of DHT, or 0.3 nM of DHT and the tested compound. At the end of incubation, the medium was removed and then cells were lysed with $20 \mu \mathrm{l}$ of lysis buffer $[25 \mathrm{mM}$ Tris-HCl ( pH 7.8 ), 2 mM dithiothreitol, $2 \mathrm{mM} 1,2$-cyclohexanediamine-tetraacetic acid, $10 \%$ glycerol and $1 \%$ TritonX-100]. Luciferase substrate $[20 \mathrm{mM}$ Tris- $\mathrm{HCl}(\mathrm{pH} 7.8), 1.07 \mathrm{mM}$ $\left(\mathrm{MgCO}_{3}\right)_{4} \mathrm{Mg}-(\mathrm{OH})_{2} \cdot 5 \mathrm{H}_{2} \mathrm{O}, 2.67 \mathrm{mM} \mathrm{MgSO} .7 \mathrm{H}_{2} \mathrm{O}, 0.1 \mathrm{mM}$ EDTA, 33.3 mM dithiothreitol, 0.27 mM coenzyme A, 0.47 mM luciferin, 0.53 mM ATP] was added and luciferase activity was measured with a ML3000 luminometer (Dynatech Laboratories). AR antagonistic activities were calculated by formula below;

AR antagonistic activity (\%) = 100(I-X)/(I-B)
I: (luciferase activity of AR/CHO\#3)/(luciferase activity of SV/CHO\#10) in the presence of 0.3 nM of DHT
B: (luciferase activity of AR/CHO\#3)/(luciferase activity of SV/CHO\#10) in the presence of DMSO
X: (luciferase activity of AR/CHO\#3)/(luciferase activity of SV/CHO\#10) in the presence of 0.3 nM of DHT and the tested compound

The concentration of compounds showing $50 \%$ of AR antagonistic activities, $\mathrm{IC}_{50}$ values, were obtained by nonlinear analysis using Statistical Analysis System (SAS).

In vivo evaluation of antiandrogenic activities in castrated immature rats [25]
Treated with Androgen Male Wistar rats were obtained from the Animal House Colony, Research Institute of Ophthalmology, Giza, Egypt. Prepubertal male rats aged 3 weeks were castrated by the scrotal route under ether anesthesia. Three days after the castration, testosterone propionate (TP, $0.5 \mathrm{mg} / \mathrm{kg}$, s.c.) was administered once daily for 5days alone or in combination with the tested compound ( $10-30 \mathrm{mg} / \mathrm{kg}$, p.o.). TP was dissolved in cotton seed oil containing $5 \%$ ethanol. The tested compound was suspended with $0.5 \%$ methylcellulose. The rats were sacrificed by excessive chloroform anesthesia 6 h after final dosing, and both ventral prostates and seminal vesicles-coagulate glands were removed and weighed. The antiandrogenic activity was expressed as a percentage of inhibition of the TP effect (TP-treated rats were arbitrarily assigned a value of $0 \%$ and vehicle-treated rats a value of $100 \%$ ).

In vitro anti-tumor screening on different prostate cell lines [26, 27]
Compounds were subjected to in vitro disease-oriented primary antitumor screening. Different prostate cell lines of tumor cell lines were utilized. The tumor cell lines of the cancer screening panel were grown in RPMI 1640 medium containing $5 \%$ fetal bovine serum and 2 mM L-glutamine. For a typical screening experiment, cells were inoculated into 96 -well micro-titer plates in 100 mL at plating densities ranging from 5000 to 40,000 cells $/$ well depending on the doubling time of individual cell lines. After cell inoculation, the micro-titer plates were incubated at $37^{\circ} \mathrm{C}, 5 \% \mathrm{CO}_{2}, 95 \%$ air, and $100 \%$ relative humidity for 24 h prior to addition of experimental drugs. After 24 h , two plates of each cell line were fixed in situ with TCA, to represent a measurement of the cell population for each cell line at the time of drug addition. Experimental drugs were solubilized in DMSO at 400 -fold the desired final maximum test concentration and stored frozen prior to use. At the time of drug addition, an aliquot of frozen concentrate was thawed and diluted to twice the desired final maximum test concentration with complete medium containing $50 \mathrm{mg} \mathrm{mL}^{-1}$ gentamicin. Additional four 10 -fold or $1 / 2 \log$ serial dilutions were made to provide a total of five drug concentrations plus control. Aliquots of 100 mL of these different
drug dilutions were added to the appropriate microtiter wells already containing 100 mL of medium, resulting in the required final drug concentrations. Following drug addition, the plates were incubated for an additional 48 h at $37^{\circ} \mathrm{C}, 5 \% \mathrm{CO}_{2}, 95 \%$ air, and $100 \%$ relative humidity. For adherent cells, the assay was terminated by the addition of cold TCA. Cells were fixed in situ by the gentle addition of 50 mL of cold $50 \%$ ( $\mathrm{w} / \mathrm{v}$ ) TCA (final concentration, $10 \% \mathrm{TCA}$ ) and incubated for 60 min at $4^{\circ} \mathrm{C}$. The supernatant was discarded, and the plates were washed five times with tap water and air dried. Sulforhodamine B (SRB) solution ( 100 mL ) at $0.4 \%(\mathrm{w} / \mathrm{v})$ in $1 \%$ acetic acid was added to each well, and plates were incubated for 10 min at room temperature. After staining, unbound dye was removed by washing five times with $1 \%$ acetic acid and the plates were air dried. Bound stain was subsequently solubilized with 10 mM trizma base, and the absorbance was read on an automated plate reader at a wavelength of 515 nm . For suspension cells, the methodology was the same except that the assay was terminated by fixing settled cells at the bottom of the wells by gently adding 50 mL of $80 \% \mathrm{TCA}$ (final concentration, $16 \% \mathrm{TCA}$ ). The parameter used here is $\mathrm{GI}_{50}$ which is the $\log 10$ concentration at which PG is 50 , was calculated for each cell line.

## Anti-prostate cancer screening anti-androgenic bioassay in human prostate cancer cells

 [28]Human prostate cancer LNCaP and PC-3 cells were maintained in RPMI medium and Dulbecco's minimum essential medium (DMEM), respectively. Both media were supplemented with penicillin ( 25 units $/ \mathrm{mL}$ ), streptomycin ( $25 \mu \mathrm{~g} / \mathrm{mL}$ ), and $10 \%$ fetal calf serum. For the androgen receptor transactivation assay, an androgen-dependent reporter gene transcription test was employed as the primary screening for potential antiandrogen identification.

This assay was first performed in LNCaP cells, which express a clinically relevant mutant AR. Once anti-androgenic activity was detected in the LNCaP AR transactivation assay, compounds were re-examined for their potential activity against wild type AR. Wild type AR transactivation assay was performed in PC-3 host cells, which lack an endogenous, functional AR. The method and conditions of cell and gene transfection have been described previously. In brief, cells were plated in 24 -well tissue culture dishes for 24 (PC-3 cells) or 48 ( LNCaP cells) h prior to transfection. Subsequently, LNCaP cells were transfected with a reporter gene, MMTV-luciferase, which contains MMTV-LTR promoter and androgen receptor binding element, and PRL-SV40, which served as an internal control for transfection efficiency. PC-3 cells were transfected with a wild type AR expression plasmid, pSG5AR, in addition to the above-mentioned MMTV-luciferase reporter gene and PRL-SV40 internal control. SuperFect (Qiagen, Chatsworth, CA) was employed as the transfection reagent following manufacturer's recommendations. At the end of a five-hour transfection, the medium was changed to DMEM or RPMI supplemented with $10 \%$ charcoal dextran-stripped, i.e., androgen-depleted, serum. After 24 h , the cells were treated with 1 nM of DHT and/or test compounds at the designated concentration for another 24 h . The cells were harvested for luciferase activity assay using Dual Luciferase Assay System (Promega, Madison, WI). The derived data were expressed as relative luciferase activity normalized to the internal luciferase control. Cells cultured in medium containing DHT (androgen), as a positive control, induced a marked reporter gene expression. Test compounds capable of significantly suppressing this DHT-induced reporter gene expression were identified as potential antiandrogens.

## EGFR and VEGFR-2 kinase activity assays by ELISA [29]

The assay was performed in 96 -well plates pre-coated with $20 \mu \mathrm{gLL}{ }^{-1}$ poly (Glu, Tyr)4:1 (Sigma) as a substrate. In each well, $85 \mu \mathrm{~L}$ of an $8 \mu \mathrm{M}$ ATP solution and $10 \mu \mathrm{~L}$ of the compound were added at varying concentrations. Sorafenib was used as a positive control for VEGFR-2 and EGFR kinase, and $0.1 \%(\mathrm{v} / \mathrm{v})$ DMSO was the negative control. Experiments at each concentration were performed in triplicate. The reaction was initiated by adding $5 \mu \mathrm{~L}$ of VEGFR-2 or EGFR kinase. After incubation for 1 h at $37^{\circ} \mathrm{C}$, the plate was washed three times with PBS containing $0.1 \%$ Tween 20 (T-PBS). Next, $100 \mu \mathrm{~L}$ of anti-phosphotyrosine (PY99; 1:500 dilution) antibody was added. After 1 h of incubation at room temperature, the plate was washed three times. Goat anti-mouse IgG horseradish peroxidase ( $100 \mu \mathrm{~L} ; 1: 2000$ dilution) diluted in T-PBS containing 5 $\mathrm{mg} \mathrm{mL}^{-1}$ BSA was added. The plate was reincubated at room temperature for 1 h , and washed as
before. Finally, $100 \mu \mathrm{~L}$ of developing solution $\left(0.03 \% \mathrm{H}_{2} \mathrm{O}_{2}, 2 \mathrm{mg} \mathrm{mL}^{-1}\right.$ o-phenylenediamine in citrate buffer $0.1 \mathrm{M}, \mathrm{pH} 5.5$ ) was added and incubated at room temperature until color emerged. The reaction was terminated by the addition of $100 \mu \mathrm{~L}$ of $2 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$, and A 492 was measured using a multiwell spectrophotometer (VERSAmax ${ }^{\text {TM }}$ ). The inhibition rate (\%) was calculated using the equation : Inhibition rate $(\%)=\left[1-\left(\mathrm{A}_{492} / \mathrm{A}_{492 \text { Control }}\right)\right] \mathrm{X} 100 \%$

## Determination of acute toxicity $\left(L D_{50}\right)$

The $L D_{50}$ was determined by using rats. They were injected with different increasing doses of the synthesized compounds. The dose that killed $50 \%$ of the animal was calculated according to Austen et al. 1961 [30].

## 3. Results and discussion <br> Chemistry

In continuation of our previous work, a series of steroidal arylidine and pyazoline candidates 1-11 (Figs. $3 \& 4$ ) were synthesized before [31]. Herein, we report the activities of these compounds for evaluation as anti-androgenic, anti-prostate cancer and EGFR, VEGFR-2 kinase inhibitor agents.

## Pharmacological Activities

Anti-androgenic activities
All the synthesized compounds were tested for their transcriptional activity for Human androgen receptor, the authors found that all the compounds except derivatives (1a-e, 2a-e) and (7a-c) having in vitro androgen Receptor (AR) Antagonistic Activities (Table 1). The obtained good data tabulated in Table 1 prompted the author to screen these compounds for their in vivo anti-androgenic activities in Castrated Immature Rats, the authors found that all the tested compounds except derivatives (1a-e and 2a-e) and (7a-c) having anti-androgenic activities (Table $2)$.

Anti-prostate cancer
All the tested compounds were screened as antitumor activities in different prostate cell lines namely, LNCaP-Rf, BM18, pRNS-1-1/ras, RC58T/hTERT and PPC-1. From the resulting data in Tables 3 and 4, all these compounds except derivatives (1a-e, 2a-e) and (7a-c) stopped the growth of the prostate cancer in these prostate cancer cell lines (Tables 3a and 3b). Anti-prostate cancer screening anti-androgenic bioassay in human prostate cancer cells were done for all the tested compounds depending on the light of the previous obtained data (Tables 1-3) and
calumniated on all these compounds except derivatives (1a-e, 2a-e) and (7a-c) were founded to be active (Table 4).

| 11b | $0.39 \pm 7 \times 10^{-14}$ | $0.03841 \pm 5 \times 10^{-17}$ |
| 11c | $0.40 \pm 5 \times 10^{-14}$ | $0.05532 \pm 5 \times 10^{-17}$ |

All data represent mean values for 8 separate experiments. Average and average $\pm$ SE, $\mathrm{n}=8$, Statistical comparison of the difference between control group and treated groups was done by one way ANOVA and Duncan's multiple comparison test $* \mathrm{P}<0.05$.

## EGFR and VEGFR-2 kinase inhibitor activities

Aiming to clarification the anticancer activities both the EGFR and VEGFR-2 kinase activity assay by ELISA were done for all the newly synthesized compounds and calumniated on all these compounds except derivatives (1a-e, 2a-e) and (7a-c) were founded to be EGFR and VEGFR-2 kinase inhibitor activities (Table 5).

Table 5: Enzymatic inhibition (VEGFR-2/EGFR) of the synthesized compounds

## 4. Conclusion

The pyrazoline derivatives provided the highest androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities (derivatives 5, 6, 10 and 11) (Table 5). NPropinoyl pyrozline derivatives ( $\mathbf{6}$ and 11) were less active as androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities than the deacylated ones (5 and 10), the high activities of the later derivatives due to the free lone pair of electrons on the NH atom that capable of forming hydrogen bonding with the receptor sites. Careful examination of all the data obtained leads to the following facts and assumptions. Opening the pyrazoline ring decreases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities (derivatives $\mathbf{3 , 4 , 8}$ and 9 ) due to conformational changes in molecule cage where the strain present in the pyrazoline moiety facilitate approach and binding with the receptor site due to small size and tight cage (derivatives $\mathbf{5 , 6 , 1 0}$ and $\mathbf{1 1}$ specially in 5 and $\mathbf{1 0}$ ) while the open hydrazine part is slightly planner and spread over the receptor with no complete fitting characters, this hypothesis supported by the activities of the smaller size 16 -methoxyl (derivatives $\mathbf{4}$ and $\mathbf{8}$ ) were high than that of those of the biggest 16-ethoxyl (derivatives 3 and 9) due to also the same reason where the methoxyl is less stereo hindered than the ethoxyl and permit approach and fitting to the receptor binding sit.

The $3 \beta$ - trifluoroacetoxyl decreases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities (derivatives 2 to $\mathbf{6}$ ) than the $3 \beta$-acetoxyl ones (derivatives 7 to 11) due to high strict hindrance of the fluoride atom that make crowdedness that
hinders the approach and active fitting receptor site than the smaller hydrogen one. The fluoride atom on the aromatic moiety increases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities more than the bromide ones because the fluoride is of high inductive effect plus smaller in size some induces and permits approach and fitting to the active receptor sites.

The methoxyl group with +M decreases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities than that of the halide atom with -I , the same happens with slightly neutral group as methyl one due to charge accumulation with +M and charge separation with -I effects that play major role with attraction to the receptor clouds and neighboring (-I) and reputation with ( +M ). The arylidene derivatives 2 and 7 completely devoid from any androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities probably due to the absence of any nitrogen binding site and the remote cage effects that can it induces it.

## Structure Activity Relationship (SAR)

- The pyrazoline derivatives provided the highest androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities (derivatives 5, 6, 10 and 11).
- N-propionyl pyrozline derivatives ( $\mathbf{6}$ and 11) were less active as androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities than the deacylated ones ( $\mathbf{5}$ and 10).
- Opening the pyrazoline ring decreases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities (derivatives $\mathbf{3 , 4 , 8}$ and $\mathbf{9}$ ) .
- The $3 \beta$ - trifluoroacetoxyl decreases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities (derivatives 2 to 6) than the $3 \beta$-acetoxyl ones (derivatives 7 to 11).
- The fluoride atom on the aromatic moiety increases the androgen Receptor, antiprostate cancer and EGFR and VEGFR-2 kinase inhibitor activities more than the bromide ones.
- The methoxyl group with +M decreases the androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities than that of the halide atom with -I , the same happens with slightly neutral group as methyl one due to charge accumulation with +M and charge separation with $-I$ effects that play major role with attraction to the receptor clouds and neighboring (-I) and reputation with ( +M ).
- The arylidene derivatives ( 2 and 7) completely devoid from any androgen Receptor, anti-prostate cancer and EGFR and VEGFR-2 kinase inhibitor activities.
